The Cadastral Template 2.0, From Design to Implementation

Abbas RAJABIFARD (Australia), Daniel Steudler (Switzerland), Ali AIEN, and Mohsen KALANTARI, Australia

Key words: Cadastral Template 2.0, Cadastral Template Project, Land Administration, PCGIAP

SUMMARY

In 2003, the Cadastral Template Project (http://www.cadastraltemplate.org/) completed gathering data on four key issues under the support of the UN-sponsored PCGIAP Working Group 3 on Cadastre. These key issues are: the magnitude of the basic tasks in the cadastral system; the magnitude and problems involved in the informal occupation of land; the role of the cadastre in SDI, and to get an appreciation of the completeness, comprehensiveness, use and usefulness of spatial cadastral data; and lastly, to get an understanding of the capacity building activities in place or which are needed to be established to support the system. The Cadastral Template Project has collected data on 47 different national cadastral systems with updated reports being provided regularly by countries, demonstrating the continued merit of the exercise. However, in line with new technologies, the evolving conceptualisation of the role of the cadastre and an increasing focus on spatially enabled societies, an evolution of the project is now in the pipeline.

This paper presents a new platform for the template, Cadastral Template 2.0. It will be a web-based resource that will gather and authenticate information through an enabling platform that is equipped with new functionalities and flexible design for updating and populating information about cadastres. Cadastral Template 2.0 will also be designed to reflect the increasing acknowledgement of the relationship between cadastres and the concept of spatially enabled societies. Data of those 47 countries has been already moved into the Cadastral Template 2.0 and it can be updated by the authorised users.

The Cadastral Template 2.0, From Design to Implementation

Abbas RAJABIFARD (Australia), Daniel Steudler (Switzerland), Ali AIEN, and Mohsen KALANTARI, Australia

1. INTRODUCTION

Cadastres are regarded as the foundation for sustainable social, economic and environmental development of societies. In 2003, under the auspices of the UN-sponsored PCGIAP Working Group 3 on Cadastre, a generic cadastral template was developed to establish a standard form, which allowed cadastral organisations to present and describe national cadastral systems in a standardised format. Such standardisation was important for enabling the identification of similarities and differences in matters such as land policy, laws and regulations, land tenure issues, institutional arrangements, spatial data infrastructures, technology, human resources and efforts to support capacity building.

The Cadastral Template Project (http://www.cadastraltemplate.org/) commenced and endeavoured to gather data on four key issues (Steudler et al., 2003; 2004):
- the magnitude of the basic tasks in the cadastral system;
- the magnitude and problems involved in the informal occupation of land;
- the role of the cadastre in SDI, and to get an appreciation of the completeness, comprehensiveness, use and usefulness of spatial cadastral data; and
- to get an understanding of the capacity building activities in place or which needed to be established to support the system.

A decade on, the Cadastral Template Project has collected data on 47 different national cadastral systems with updated reports being provided regularly by countries, demonstrating the continued merit of the exercise (Country Report, 2003). However, in line with new technologies, the evolving conceptualisation of the role of the cadastre and an increasing focus on spatially enabled societies, an evolution of the project is now in the pipeline.

This paper presents a new platform for the template, Cadastral Template 2.0. It will be a web-based resource that will gather and authenticate information through an enabling platform that is equipped with new functionalities and flexible design for updating and populating information about cadastres. Cadastral Template 2.0 will also be designed to reflect the increasing acknowledgement of the relationship between cadastres and the concept of spatially enabled societies (Rajabifard and Steudler, 2013). In addition to continuing to collect cadastral-related data, Cadastral Template 2.0 will also seek to gather data on the key elements that have been identified for a spatially enabled society, as outlined in FIG Publication No. 58, 'Spatially Enabled Society':

- legal framework;
- common data integration concept;

TS 7 – Cadastre and Land Management
Abbas Rajabifard, Daniel Steudler, Ali Aien, and Mohsen Kalantari
The Cadastral Template 2.0, From Design to Implementation

- positioning infrastructure;
- spatial data infrastructure;
- land ownership information; and
- data and information.

It is envisioned that this new platform of data will provide a fundamental resource to assist countries in assessing and benchmarking their own national systems. This ultimately will facilitate the decision-making process in land administration systems and bring efficiency to their processes.

2. Web 2.0

Web 2.0 concepts encourage end users to interact and communicate with the web, rather than being a simple web reader. Web 2.0 (websites, social media, etc) allows users to do more than just retrieve information. A user is invited to 'write' as well, instead of purely 'reading', or contribute to the content available to everyone in a user friendly way. By increasing Web 1.0 features, the user has more user-interface, software and storage facilities, all through their browser (O'Reilly, 2005). Cadastral Template Project was designed successfully based on Web 1.0 concept in 2003. However, existing of new technologies (technology push) and also the user demand to utilise these technologies led to develop Cadastral Template 2.0 based on Web 2.0 concepts.

3. Cadastral Template 2.0, Design

3.1 Technologies used in the Cadastral Template 2.0

The following web-based programming technologies have been used in this template:

- Database
  - MySQL: to store and maintain cadastral data provided by the individual participants.

- Back-end Technology
  - PHP: a server-side scripting language to communicate and retrieve the data from the database.

- Front-end Technology
  - JavaScript: client-side scripts to interact with the user and visualised the retrieved data.
  - JQuery: to simplify the client-side scripting of HTML.
  - Datamaps: a SVG-based data maps using D3.js to provide some data visualisations based on geographical data.
  - D3.js: a JavaScript library that uses digital data to drive the creation and control of dynamic and interactive graphical form.

TS 7 – Cadastre and Land Management

The Cadastral Template 2.0, From Design to Implementation

        o   Google Chart API: A Google API to create charts from some data and embed it in a web page.

3.2 Architecture of the Template

3.2.1 Interactive Map and Visualisation features

Architecture of Cadastral Template 2.0 is based on providing interactive mapping services and visualisation features for end users. This helps users of the template to analyse and compare different data and supports decision making for improving their cadastral systems based on the findings from the template. Figure 2 shows the designed interactive map of Cadastral Template 2.0. Using this interactive map, users can perceive the distribution of countries which participated in this template.

As it can be seen in figure 1, there is a gap in participation from North and South America, Africa, and Middle East regions. The ultimate goal of this architecture is to ease the data manipulation and updating process to encourage more participants.

3.2.2 Open Source and free licensed technologies

Also, all the deployed web technologies which are used in Cadastral Template 2.0 are open source and they have free licensing systems. This provides more opportunities for other developers and increases engagement to improve this template.

3.2.3 Regional-based and country-based classes

In Cadastral Template 2.0, countries are divided into 6 regions respectively Asia, Europe, Africa, North America, South America, and Oceania (Figure 1). This regional-based classification facilitates analysing and comparing different cadastral data within a region or inter-regions.

3.2.4 Principles and Statistics

Cadastral Template 2.0 provides predefined statistical analysis based on the provided data by the participants. This data is retrieved from the database. Section 4.1 will provide further detain about this function.

4. Cadastral Template 2.0, Implementation

In this section, we will navigate into different parts of the template to demonstrate the existing functionalities of Cadastral Template 2.0. The end user can select a country, via clicking on a country or selecting from the table which links to new page containing two buttons: Country Context and Country Principles. Figure 2 shows these buttons for the selected country, Australia.

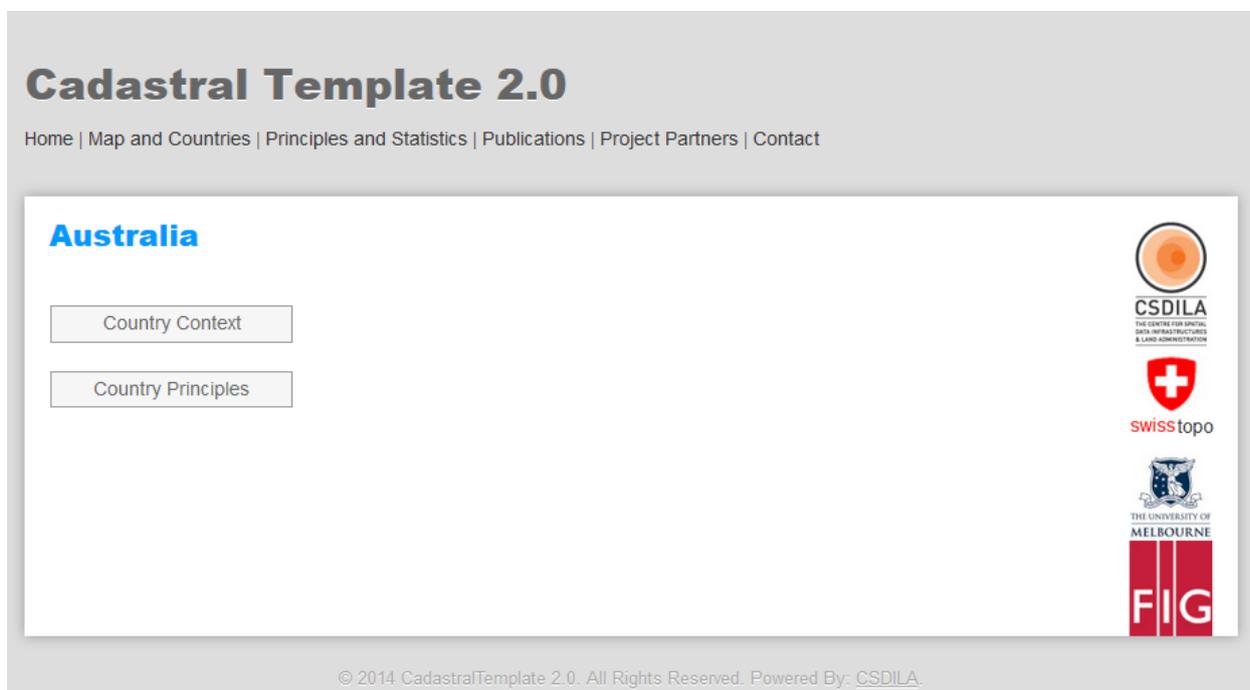

Figure 2. Country Context and Country Principles for Australia

Country Context covers demographic information, institutional framework, and cadastral systems, mapping, and issues for each individual country. Table 1 lists the materials which are maintained in the Country Context section.

Australia

Update Country Context information

Country Context

Geographical Context

Australia is the largest island continent in the world, with a total area of over 7,600,000 sq km, lying south of the Equator between the Indian and South Pacific Oceans. The population is approximately 19.5 million, with a growth rate of about 1%. The majority of the population (85%) resides in urban areas along the east and southeast coastline and fertile plains. Much of the interior of the country is flat, barren and sparsely populated. The highest point, Mt Kosciuszko reaching 2,229m, is within an extensive mountain range running north south along the eastern seaboard. Australia also lays claim to the third largest marine jurisdiction in the world and has a coastline extending more than 36,700km.

Historical Context

Australia was colonized in 1788, although was inhabited for over 40,000 years by the indigenous Aboriginal peoples. Australia has been an independent member of the British Commonwealth since 1901 when it became a Federation of States. A referendum to change Australia's status from a Commonwealth headed by the British monarch to a republic, was defeated in 1999 and hence Queen Elizabeth II of England remains the Head of State.

Current Political and Administrative Structures

The constitution vests in the Governor-General, representing the Head of State exercised by tradition on behalf of the elected government. The Government is based on a bicameral Federal Parliament headed by an elected Prime Minister consisting of a Senate which has proportional representation among the States. The Federal Government has powers over defence, foreign affairs, trade and commerce, taxation, customs and excise duties, pensions, immigration and postal services. Other powers are left with the States, such as health, education, state transport networks, town and rural planning and land administration (cadastral system, land registration).

Historical Outline of Cadastral System

Although inhabited for over 40,000 years by the Aboriginal peoples, their land rights did not gain legal recognition until 1993 with the introduction of the Indigenous Native Titles Act. The development of the Australian cadastral system was not influenced by the land ownership systems or patterns of the indigenous peoples. Instead from the initial colonization period of 1788 Australia began adopting the English system of deeds registration for land transfer. It was not until the mid 1850s in the colony of South Australia that Robert Torrens introduced the system of Certificate of Title to simplify land transfer, which had become expensive, complicated and inefficient. By 1874 all States of Australia had adopted the "Torrens System" of title registration. Settlement surveys were hampered by harsh terrain, unrecognizable land marks, rapid settlement and a shortage of professional surveyors leading to a sporadic approach to surveying and a lack of survey control. Cadastral maps were based on isolated surveys of Parish areas at a scale of 1inch to 20 chains, primarily for registration of private title (freehold land) and reservation of Crown land. Certificates of Title were registered at a central Land Titles Office in each State where details of mortgages, easements, covenants and leases are registered.

Institutional Framework

Government Organizations

5. Conclusions

The cadastral template project was a first step to collect generic information about cadastral and land administration systems. Technology push and user demand pull led to upgrade the existing cadastral template to a Web 2.0 based template. Cadastral Template 2.0 contains cadastral data of all 47 countries. It allows the authorised users to edit the data, make queries and compare the data of different countries and regions. Cadastral Template 2.0 has an interactive map allows users to find the coverage area of the template and easy access to the information of interested countries. However, there are many more features and aspects such as the cadastral processes of land transfer, subdivision and 3D cadastres (Aien, 2013); etc. that would deserve further investigation. This project aims at the most basic to provide Web 2.0 concepts for the users. However, it will provide the basis for further research and future data collection.

Abbas Rajabifard is a Professor and Head of Department of Infrastructure Engineering at The University of Melbourne. He is also Director of the Centre for Spatial Data Infrastructures & Land Administration (CSDILA). He is former President of the GSDI Association, a member of ICA-Spatial Data Standard Commission, and a member of Victorian Spatial Council.

Daniel Steudler graduated from the Swiss Federal Institute of Technology (ETH) in Zurich in 1983, earned the Swiss license for licensed land surveyor in 1985, and did his M.Sc.Eng. degree at the University of New Brunswick, Canada from 1989-91. Since 1991, he is working with the Swiss Federal Directorate of Cadastral Surveying with the responsibilities of supervising and consulting Swiss Cantons in organisational, financial, technical, and operational matters in cadastral surveying. Since 1994, he is involved in the activities of FIG-Commission 7 as a working group secretary, and in 2003, he became the official Swiss delegate to Commission 7. In February 2004, he completed the requirements for a PhD degree at the Department of Infrastructure Engineering, the University of Melbourne.

Ali Aien completed his PhD in 2013 at the Department of Infrastructure Engineering, the University of Melbourne. His research aimed to develop and implement a data model for 3D cadastre. He is currently working as a research assistant in the Centre for Spatial Data Infrastructures & Land Administration (CSDILA).

Mohsen Kalantari is a lecturer at the Centre for SDIs and Land Administration at the Department of Infrastructure Engineering, the University of Melbourne working on 3D cadastre. He finished his PhD from the University of Melbourne in 2008.
